Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Descripti n

The invention describes an improved etched abrasive tool plate for surface smoothing, and a method to produce it. A tool in accordance with the preamble of claim 1 and, respectively, a method in accordance with the preamble of claim 8 are known, for example, from GB-A- 2 166 676.

It is previously known to produce tools for abrasive surface smoothing of workpieces of wood, plastics, leather and other soft materials by etching a thin flat steel plate, so that from the original surface of the plate only minor parts remain as flat limited surface portions with round, elongated or polygonal shape. The other parts of the plate surface are by the etching recessed to a lower level. The remaining flat surface portions then form the tips of cutting elements protruding from the recessed etched surface, and shaped like truncated cones or pyramids, as described in U.S. patent 3,045,321, where the edges of the flat surface portions constitute the cutting edges in abrasive smoothing of the workpiece.

This type of tool plate can produce very smooth surfaces on the workpiece, but requires that the tool is pressed against the workpiece with enough force to cause the cutting elements to penetrate a small distance into the workpiece. For small tools or convex workpieces this poses no problem. For large flat workpieces and large tools, such as orbital sanders the force would be too large to be practical, however.

Different methods have been suggested to facilitate the use of etched tool plates also in this case. U.S. patent 3,045,321 suggests the possibility of etching until the flat surface portions on the tips of the cutting elements become very small or vanish. In such a case, however, one would not achieve a good smooth workpiece surface but a finely scratched, even though flat. Very small tip surfaces would also make it impossible to etch in such a manner that the cutting edge angle becomes less than 90 degrees with the upper portion of the cutting elements hourglass-shaped, as has otherwise proved advantageous, especially to get highest surface smoothness.

JP patent 60-19648 describes that one can perform further etching steps to make the flat surface portions coarse and irregular, which facilitates their penetration into the workpiece. This is only a temporary effect, however, since the surface portions quickly become smooth and flat through wear when used.

The present invention describes an etched tool plate and a tool plate and a method for producing it, where through a special forming operation the load is distributed between the cutting elements in such a way that only a minor number of them carry

the full load and at the same time limit the penetration of other cutting elements which are given improved abrading ability by tilting. In this manner large flat tool plates can be manufactured, which simultaneously achieve better surface smoothness, lower forces and better wear resistance than previously known tool plates.

The invention is described below with reference to the accompanying figures, where

Fig. 1 shows a section through an etched tool plate with cutting elements according to known technology,

Fig. 2 shows a section through an improved etched tool plate according to the present invention,

Fig. 3 shows a plan view of the etched side of an improved tool plate according to the invention.

In Figures 1-3 the cutting elements (11) with flat tip surface portions (12) are shown protruding from the etched tool plate (10).

To produce an improved tool plate according to the invention, one starts with a thin steel plate, on which as is previously known from U.S. patent 3,045,321 a material resistant to etching fluid is applied on one side in a determined pattern such as equal size spots which can be round, elongated or polygonal. The application can be performed through some printing process such as silk-screen printing, or by covering the whole plate with a layer of water-soluble photoresist, which is thereafter hardened by ultra-violet radiation in spots, after which the non-hardened parts of the layer are flushed away. The side of the plate with the resistant pattern is then sprayed with an etching fluid, such as ferric chloride dissolved in water, so that those parts of the surface not protected by the resistant pattern elements are etched away to a determined depth, while those parts protected by the resistant pattern elements remain as protruding cutting elements. Through variation of spraying mode, composition and temperature of the etching fluid one can influence the angle between the side of the protruding cutting elements and the original plate surface, as well as how far under the edge of the protecting pattern elements the etching will reach.

After the etching process and cleaning, the tool plate (10) corresponds to what is known from U.S. patent 3,045,321 which is usable for surface smoothing but has the drawbacks mentioned and is not suitable for large flat tools. According to the invention the plate is then rolled twice between one rigid roller with raised parallel strips and one elastically deformable roller made with rubber or polyurethane, with the rigid roller in contact with the unetched backside of the tool plate, and the elastically deformable roller in contact with the etched side. Through this rolling the tool plate is deformed

with parallel ridges (13, 14) on the etched side. The sharpness of the ridges depends on the width of the parallel strips. After rolling twice in a row producing ridges with different directions, the ridges form a system of rhombic quadrangles, which prevents the plate from curling, as it would do if all ridges were in the same direction.

Preferentially, the longer axis of the rhombic quadrangles should coincide with the lengthwise direction of the tool plate. The distance between ridges (13, 14) should be considerably larger than the distance between the cutting elements (11).

The tool plate (10) can thereafter be attached to a flat tool plate carrier in known manner such as with glue or with textile fasteners. The tool plate carrier can be used by hand or with a sander machine.

The parallel strips on the roller can be placed tangentially or in a preferred embodiment helically like a thread around the roller. By rolling the first time with a right hand threaded and the second time with a left hand threaded roller or vice versa, the rhombic system of ridges is produced during continuous feeding of tool plate in strip form.

The rolling to form ridges has two effects, which together contribute to the superior performance of this tool plate. Those cutting elements (11) which are situated on the crest of the ridges are only a minority of the total number, and are in cutting contact with the workpiece already at low load on the tool plate. Their tip surface portions are parallel to the mean plane of the tool plate and the tool carrier and have limited abrasive capacity, but at low loads they ensure good surface smoothness, and at high loads they carry a major part of the load, and prevent overloading of other cutting elements.

Those cutting elements (11 a) which are situated on the slopes of the ridges (13, 14) are not in cutting contact with the workpiece until the load on the tool plate is increased, and do never themselves carry much of this load. Since they are situated on the slopes of the ridges, their tip surface portions are slightly inclined relative to the mean plane of the tool plate carrier. The angle of inclination is still more increased because the forces between the elastic roller and the cutting element during rolling tends to bend the tips of the cutting elements (11 a) away from the crest of the ridge (13, 14). The cutting elements (11 a) on the slopes will thus touch the workpiece with the sharp cutting edge of the tip surface portion while the cutting depth is limited by the carrying action of the cutting elements (11) on the crests. In this way one avoids overloading and damage to the cutting elements (11 a) on the slopes, which retain their sharpness longer.

After long progressive wear the needed load on

the tool plate will increase, but not as much as for a tool plate without ridges, and cutting elements situated further down the slopes will gradually take part in the abrasive cutting.

The height of the ridges (13, 14) should be of the same order as the height of the cutting elements (11) or slightly less. Otherwise the cutting elements furthest down the slopes or in the valleys will never be utilized. In practical cases the height of the cutting elements is 0.1 to 0.3 mm.

Claims

1. Etched tool plate (10) for abrasive surface smoothing of soft materials comprising a thin steel plate, one side of which has been partially recessed through etching, leaving the non-etched parts as protruding cutting elements (11) with sharp cutting edges and flat tops (12),
characterized in that the tool plate has been deformed to show parallel ridges (13, 14) on the etched side.
2. Etched tool plate according to claim 1,
characterized in that the ridges (13, 14) run in two different directions forming a pattern of quadrangles.
3. Etched tool plate according to claim 1 or 2,
characterized in that the distance between ridges (13, 14) is considerably larger than the distance between cutting elements (11).
4. Etched tool plate according to claim 3,
characterized in that the cutting elements (11 a) situated on the slopes of the ridges have top surfaces (12) inclined relative to the plane of the tool plate.
5. Etched tool plate according to claim 3 or 4,
characterized in that the height of the ridges (13, 14) is similar to the height of the cutting elements or slightly lower.
6. Etched tool plate according to any of claims 1 to 5,
characterized in that the height of the protruding cutting elements (11) is 0.1 to 0.3 mm.
7. Etched tool plate according to any of claims 1 to 6,
characterized in that the non-etched side through glue or textile-type fastener is attached to a tool carrier plate.
8. Method for manufacture of etched tool plate (10) as described in any of claims 1 to 7,

whereby the tool plate in known way on one surface is provided with a pattern of material resistant to etching fluid, followed by etching away to a determined depth of those parts of the surface not covered by the pattern, **characterized** in that the method comprises, after etching, rolling multiple times between one rigid roller with parallel raised strips and one elastically deformable roller.

9. Method for manufacture of etched tool plate according to claim 8, **characterized** in that the rigid roller is in contact with the non-etched side and the elastically deformable roller with the etched side.

Patentansprüche

1. Geätzte Werkzeugplatte (10) zum abschleifen-
den Oberflächenglätten weicher Materialien mit
einer dünnen Stahlplatte, von welcher eine Sei-
te durch Ätzung teilweise mit Vertiefungen ver-
sehen ist, wobei die nicht-geätzten Teile als
überstehende Schleifelemente (11) mit schaf-
fen Schleifkanten und flachen Kopfenden (12)
verblieben sind, **dadurch gekennzeichnet**,
daß die Werkzeugplatte verformt wurde, um
parallele Grate (13,14) auf der geätzten Seite
hervorzubringen.
2. Geätzte Werkzeugplatte nach Anspruch 1, **da-
durch gekennzeichnet**, daß die Grate (13,14)
in zwei verschiedenen Richtungen verlaufen
und ein Muster von Vierecken bilden.
3. Geätzte Werkzeugplatte nach Anspruch 1 oder
2, **dadurch gekennzeichnet**, daß die Entfer-
nung zwischen den Graten (13,14) beträchtlich
größer ist als die Entfernung zwischen den
Schleifelementen (11).
4. Geätzte Werkzeugplatte nach Anspruch 3, **da-
durch gekennzeichnet**, daß die Schleifele-
mente (11a), die sich auf den Schrägen der
Grate befinden, Oberseiten (12) haben, die in
Bezug auf die Ebene der Werkzeugplatte ge-
neigt sind.
5. Geätzte Werkzeugplatte nach Anspruch 3 oder
4, **dadurch gekennzeichnet**, daß die Höhe
der Grate (13,14) ähnlich der Höhe der Schleif-
elemente oder ein wenig geringer ist.
6. Geätzte Werkzeugplatte nach einem der An-
sprüche 1 bis 5, **dadurch gekennzeichnet**,
daß die Höhe der überstehenden Schleifele-
mente (11) 0,1 bis 0,3 mm beträgt.

7. Geätzte Werkzeugplatte nach einem der An-
sprüche 1 bis 6, **dadurch gekennzeichnet**,
daß die nichtgeätzte Seite mit Leim oder mit
textilem Befestigungsmittel an einer Werk-
zeugträgerplatte befestigt ist.
8. Verfahren zur Herstellung einer geätzten Werk-
zeugplatte (10) wie in einem der Ansprüche 1
bis 7 beschrieben, bei welchem die Werkzeug-
platte auf einer Oberfläche auf bekannte Weise
mit einem Muster gegen Ätzflüssigkeit resi-
stenten Materials versehen wird, gefolgt von
Wegätzen jener Oberflächenteile, die nicht von
dem Muster abgedeckt sind, auf eine bestimm-
te Tiefe, **dadurch gekennzeichnet**, daß das
Verfahren nach dem Ätzen ein mehrfaches
Walzen zwischen einer starren Walze mit pa-
rallelen erhabenen Leisten und einer elastisch
verformbaren Walze einschließt.
9. Verfahren zur Herstellung einer geätzten Werk-
zeugplatte nach Anspruch 8, **dadurch ge-
kennzeichnet**, daß die starre Walze mit der
nicht-geätzten Seite und die elastisch verform-
bare Walze mit der geätzten Seite in Berüh-
rung ist.

Revendications

1. Outil plat décapé (10) pour le dressage de
surfaces de matériaux mous par abrasion,
comprenant une mince plaque d'acier, dont
une face a été partiellement creusée par déca-
page, en laissant subsister des parties non
décapées sous forme d'éléments coupants en
saillie (11) avec des arêtes coupantes aigües
et des sommets plats (12), caractérisé en ce
que l'outil plat a été déformé pour présenter
des nervures parallèles (13,14) sur sa face
décapée.
2. Outil plat suivant la revendication 1, caractérisé
en ce que les nervures (13,14) s'étendent dans
deux directions différentes, formant ainsi un
dessin de quadrilatères.
3. Outil plat suivant la revendication 1 ou 2, ca-
ractérisé en ce que la distance entre les nervu-
res (13,14) est considérablement plus grande
que la distance entre les éléments coupants
(11).
4. Outil plat suivant la revendication 3, caractérisé
en ce que les éléments coupants (11a) situés
sur les flancs inclinés des nervures ont des
surfaces supérieures (12) inclinées par rapport
au plan de l'outil plat.

5. Outil plat suivant la revendication 3 ou 4, caractérisé en ce que la hauteur des nervures (13,14) est analogue à la hauteur des éléments coupants, ou légèrement inférieure.
- 5
6. Outil plat suivant l'une quelconque des revendications 1 à 5, caractérisé en ce que la hauteur des éléments coupants en saillie (11) est de 0,1 à 0,3 mm.
- 10
7. Outil plat suivant l'une quelconque des revendications 1 à 6, caractérisé en ce que la face non décapée de l'outil est fixée sur une plaque de support d'outil au moyen d'une colle ou d'éléments de fixation de type textile.
- 15
8. Procédé de fabrication d'un outil plat décapé (10) tel que défini suivant l'une quelconque des revendications 1 à 7, dans lequel comme connu en soi, on applique sur une face de l'outil un dessin d'une matière résistante à un fluide de décapage, et on enlève ensuite par décapage jusqu'à une profondeur déterminée celles des parties de la surface non recouvertes par ledit dessin, caractérisé en ce qu'après le décapage l'outil est laminé plusieurs fois entre un rouleau rigide ayant des bandes parallèles en saillie et un rouleau élastiquement déformable.
- 20
- 25
- 30
9. Procédé de fabrication suivant la revendication 8, caractérisé en ce que le rouleau rigide est en contact avec la face non décapée de l'outil, tandis que le rouleau élastiquement déformable est en contact avec sa face décapée.
